

20260731 rSFMS and rMZR by infall stages

For rSFMS, it is clear that from $\log_{10}(\Sigma_*/M_\odot \text{ kpc}^{-2}) = 7.0$ to 9.0 , pre-peak (blue) galaxies' median trend is ~ 0.3 dex higher than post-peak (red) galaxies.

For rMZR, it seems there is still kind of inversion? Post-peak (red) are a bit higher $\log_{10}(\Sigma_*/M_\odot \text{ kpc}^{-2}) < 8.0$, while pre-peak (blue) are a bit higher at > 8.0 , although the median trend difference is only ~ 0.02 dex.
